**Due date:** Today, at the end of the lab period.

## Read this entire document before beginning your lab.

Make sure to locate and place the <u>PC<sup>2</sup> Lab System</u> on your desktop. The *Comp248\_Lab\_Manual* file is available on the H: drive if you don't remember how to use the system, <u>you should worry about this after completing the question</u>.

For this lab you are <u>required to fulfill all requirements exactly as described</u> in this provided document, no less, no more.

**Question**: Today's lab has a different format. You are given a *.java* file that you are to complete and submit to PC<sup>2</sup>. The file already has a *main* method (that you are **NOT** to modify) that will test your class implementation once completed.

- Name of the file you are to complete: *Train\_2.java*
- Where is it? In the .ZIP file with the lab handout
- What does it emulate? A pet dog and is called *Train 2*
- What do I do? Complete Train\_2. java file provided. Again this file already has a main method (that you are NOT to modify) that will test your implementation once completed.
   Here are all the requirements you are to fulfill exactly as described before submitting your work. Failing to do so will result in your program not working

## Implement the class *Train\_2* so that it contains:

- ✓ 3 private instance variables: *Line* of type String, *wagons* of type integer which records the number of wagons, and *isElectric* which is Boolean and indicates if it is an electric train or not.
- ✓ A default constructor which sets all of the numeric instance variables to zero and the String instance variables to null.
- ✓ A constructor with 3 parameters which sets the 3 instance variables to the corresponding values passed.
- ✓ Implement an accessor method for each of the 3 instance variable that will return the value of the instance variable. For example, the <code>getX()</code> method for the instance variable <code>Line</code> must be called <code>getLine()</code>.
- ✓ Implement a mutator method for each instance variable that will assign to the instance variable to the value passed. For example, the <code>setX()</code> method for the instance variable <code>line</code> must be called <code>setLine()</code>.
- ✓ An *equals* method: two objects of type *Train* are equal if all the attributes of both objects have the same values.
- ✓ A Boolean method bothElectric which returns true if both trains are electric and false otherwise.
- ✓ A toString function must also be provided to return the watch information in the following format:

The train on line <line> has <wagons> wagons and is electric is <isElectric>

Where < line>, < waqons> and < isElectric > are the content of the instance variables.

If you correctly implemented all of the above, running the main method will result in your program displaying **exactly**: (REMEMBER in the output:  $\circ$  is a space,  $\rightarrow$  is a tab and  $\rightarrow$  is a new line. Text in green is user input.

**Note**: the only format you need to worry about is the one of your *toString* method as the driver is already set up.

```

Now ore othey oboth oelectric otrains? of alse
```

**Note 1:** You are to expect a perfect user who will always enter valid values; that is, **do not** verify the validity of user input.

**Note 2:** The use of libraries other than *java.util.Scanner* is prohibited. Your program must work for data entered, not just the ones in the samples above.

<u>Note 3:</u> Final thought, remember that your solution is case-sensitive and space-sensitive and fulfill the above instructions carefully and precisely.

## **Reminder:**

When submitting your solution to the lab system, make sure there is no package statement at the top of your . java file as this will result in a grade of 0 (restriction of this system).
